Advance Python Assignment

Topic-1: Printing on Screen

Q1. Explain the print() function in Python.

Ans.
The print() function is used to display output to the user in Python programs. It helps in showing messages, results, and variable values on the screen. This function is very useful for checking program output and understanding how the code works. It can print different types of data like strings, numbers, and expressions. It also allows printing multiple values together in a single line. Overall, print() is an important function for both beginners and advanced users while working with Python.

Example:
```
print("Welcome to Python Programming")
```

Q2. Explain output formatting using f-strings and format() in Python.

Ans.
In Python, output formatting is used to make the printed result more readable and organized. Two common methods for formatting are f-strings and the format() method. F-strings allow us to directly include variables inside a string using curly braces, which makes the code simple and easy to read. The format() method is another way to insert values into a string by using placeholders. Both methods help in combining text and variable values in a clear and structured way.

Example:
```
name = "Shivani"
marks = 85

print(f"Student {name} scored {marks} marks")
print("Student {} scored {} marks".format(name, marks))
```
